Computing determinants by double-crossing.

Coll. Math. J. 42, No. 1, 43-54 (2011).

Summary: Charles Dodgson's method of computing determinants is attractive, but fails if an interior entry of an intermediate matrix is zero. This paper reviews Dodgson's method and introduces a generalization, the double-crossing method, that provides a workaround for many interesting cases.

Classification: H65 N35

Keywords: determinant computation
